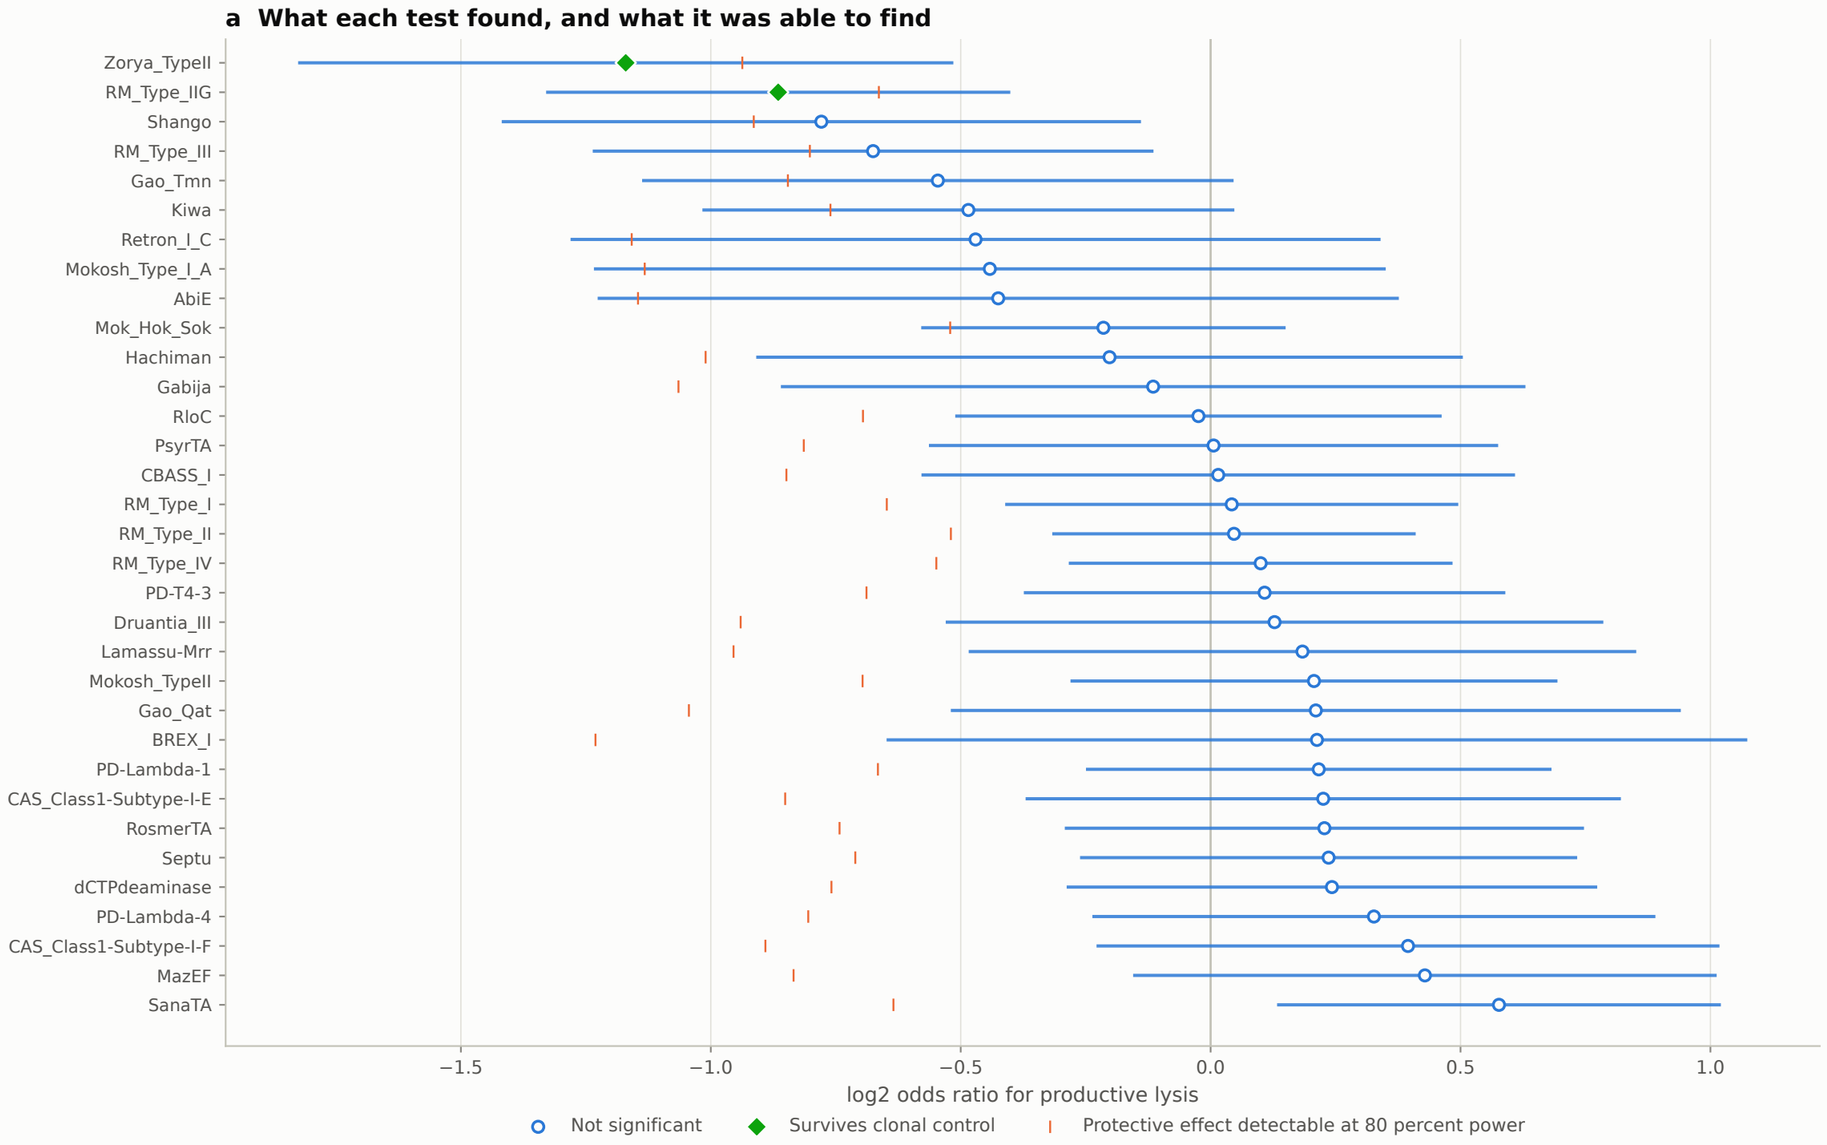
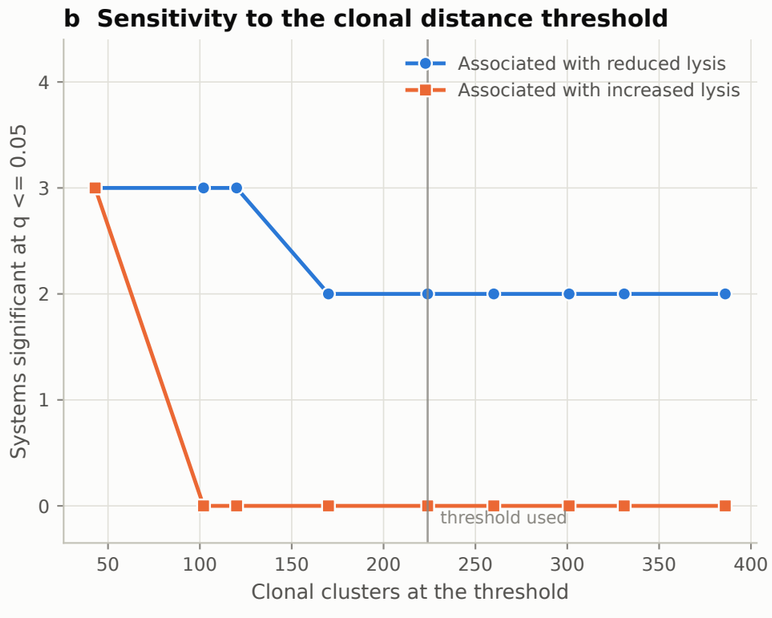
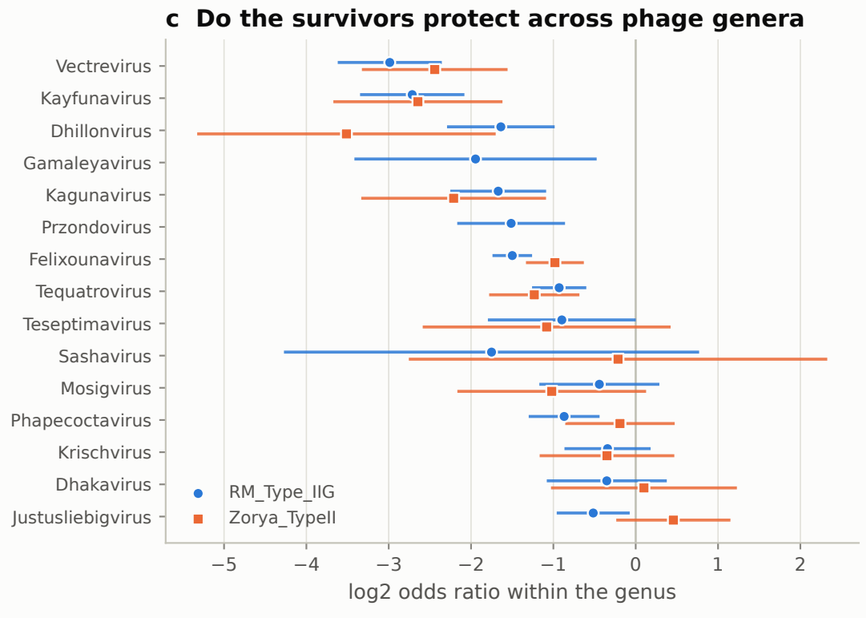
Figure 6. Neither surviving association is robust to every design, and most of the nulls are uninformative






Panel a places each system's estimate beside the protective odds ratio its own standard error would have detected at 80 percent power. Where that marker sits close to the estimate, a null excludes little, which is the case for most systems here.
2 of 33 systems survive clonal control and that count is stable across every clonal distance threshold tried, but neither survivor passes all of the stricter tests in results/robustness_report.txt. Panel c shows both are protective in direction across most phage genera.
