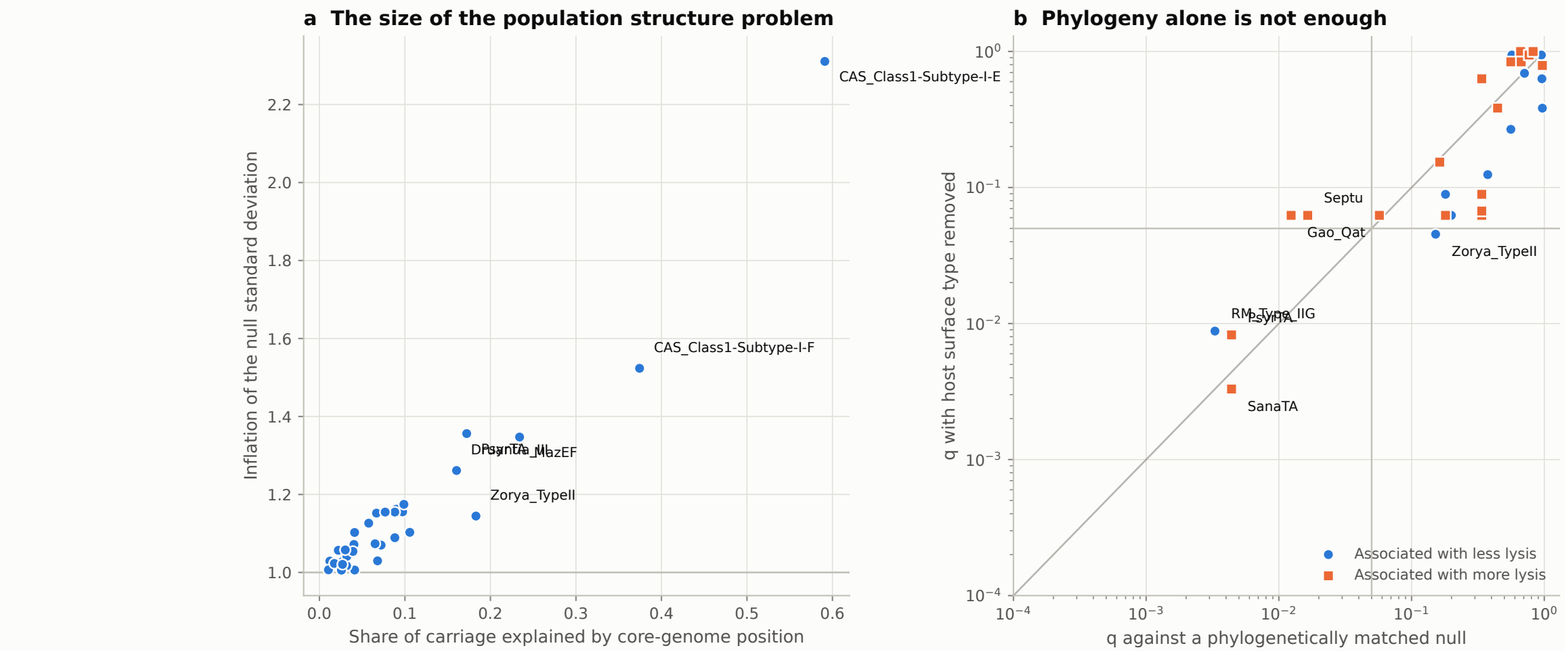
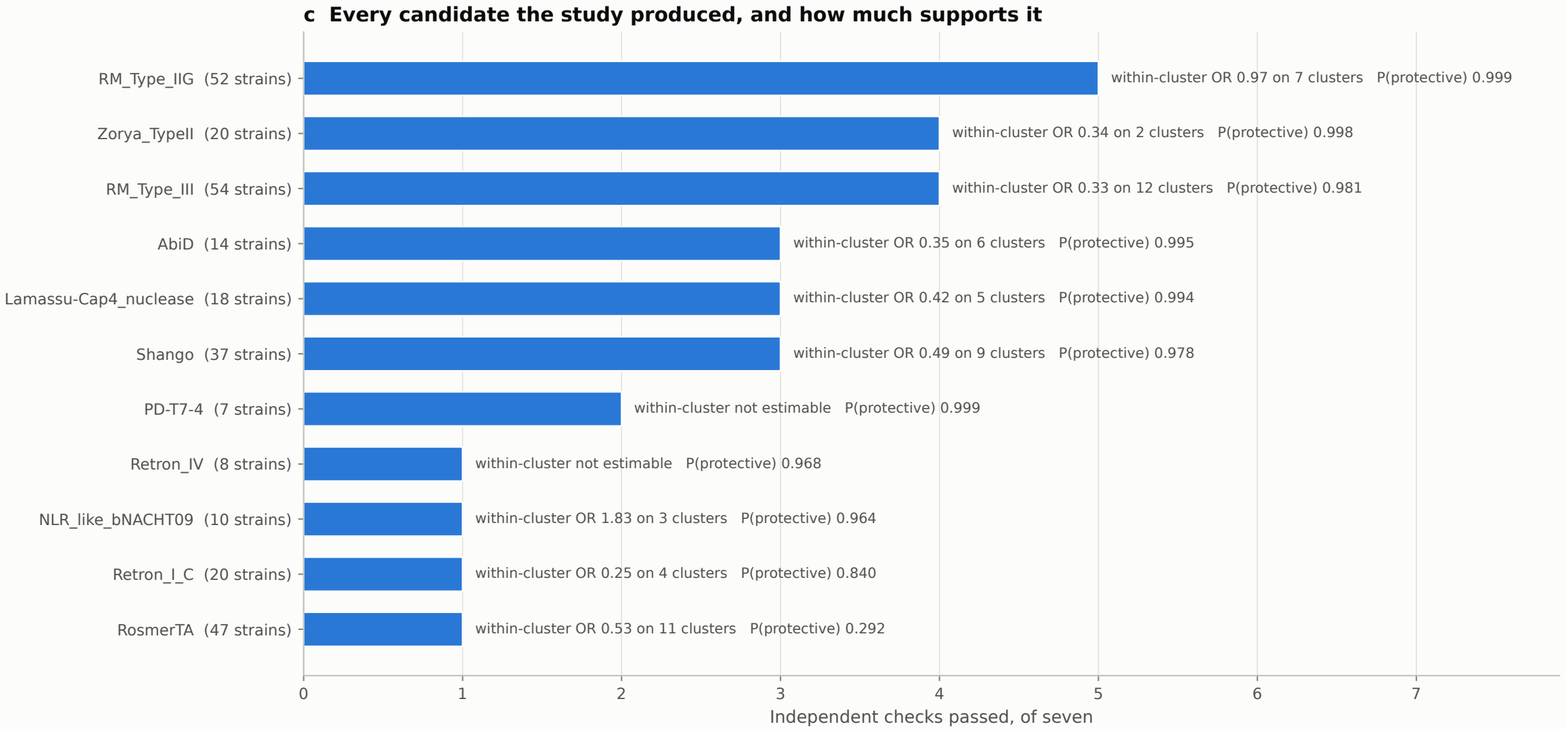
Figure 8. Harder nulls, proper posteriors, and a candidate list that no single test supports




Panel a shows that a system confined to one lineage widens the null for any test that ignores ancestry, by up to a factor of 2.3 for CRISPR-Cas subtype I-E.
Panel b compares a null matched on ancestry (5 systems significant) with the same null after host surface type is removed from the outcome (4 significant); the associations with more lysis, which no defense can cause, are the ones that move. Panel c collects every candidate; the best passes 5 of seven checks.
